

TheoreticallyPose V4 – Quick Guide

Turn any video clip into control videos for AI video generation

TheoreticallyPose converts a clip into pose skeletons, depth maps, and silhouettes – the control videos you feed to video-to-video AI tools (Seedance, Kling, Runway, and friends). Everything runs in your browser, on your machine. Your video never gets uploaded anywhere.

What you need

- Chrome or Edge on a reasonably modern computer (the depth engines use your GPU via WebGPU – Safari and Firefox may only run the skeleton and silhouette parts)
 - A video clip – a few seconds is the sweet spot; mp4 works great (a `sample_clip.mp4` is included to play with)
 - That's it. No account, no install, no subscription. It's one HTML file.
-

Quick start (60 seconds)

1. Double-click `TheoreticallyPose_V4.html` – it opens in your browser
2. Drag your clip onto the left panel (or click to browse)
3. Hit Track – it finds the person and builds the skeleton (~30s for a short clip)
4. Hit Bake in the Depth panel – it computes a depth map for every frame
5. Export MP4 (or PNG sequence) – that's your control video. Feed it to your AI video tool as the driving/reference video.

First time you Bake, the depth model downloads automatically (45–95 MB depending on engine, with a progress bar). It's cached after that – future bakes start instantly.

The layers (mix and match)

Three stackable passes, each with its own on/off and opacity:

- Skeleton – the pose stick figure. "OpenPose" colors are what most AI models were trained on; use those unless you have a reason not to.
- Silhouette – solid body shapes from the video. "Tint" style colors each person.

- **Depth** — grayscale depth of the whole scene (bright = near, dark = far).

Presets are one-click mixes: *Stick figure*, *OpenPose*, *Full Stack* (all three layers — the flagship look), *Silhouette*, *Depth only*. Watch the status bar at the bottom — every preset click tells you exactly what it switched.

The two depth engines

- **Fast** (per-frame) — quick, but each frame is computed independently, so depth can shimmer over time. The *stabilize* and *smooth* controls clean most of that up.
- **Consistent** (VDA) — a temporal model that looks at 32 frames at once. Depth comes out stable straight away — no flicker to fix — and it's actually *faster* than Fast mode on most GPUs. Needs WebGPU (Chrome/Edge). If your browser can't run it, the app tells you and Fast mode still works.

If your machine supports it, use Consistent. It's the whole reason V4 exists.

Multiple people

1. Tick **Multiple characters** and pick how many (2–5)
2. Hit **Track** again — changing the character count needs a re-track (re-tracking replaces the previous track completely)
3. Each character gets a color — you'll see numbered skeletons in the overlay. Click a character's color swatch to pick your own — it updates the skeleton tints, tinted silhouettes, and colored depth everywhere at once
4. Bonus: in the **Depth** panel, tick color chars to tint each person's region of the depth map with their character color (depth shading is preserved — near people stay bright, far people stay dark)

Tip: multi-person tracking works best when people are reasonably large in frame (roughly a third of the frame height or more). Tiny background figures may not track.

Working with a range

Set **In / Out** points (/ keys) to work on just a section — tracking, baking, and exports all respect the range. Full resets to the whole clip.

Exporting

- **Export MP4** — the composited control video, ready for your AI tool
 - **PNG seq** — a zip of lossless frames, for compositing or picky pipelines
 - **JSON** — the raw pose keypoints, if you want to do something custom
-

If something's weird

- **"Consistent engine needs WebGPU"** — use Chrome or Edge, current version. On an old GPU, use the Fast engine instead.
 - **Depth model won't download** — check your internet; the models come from HuggingFace on first use. After that it works offline.
 - **A person isn't tracking** — they're probably too small in frame, or heavily cut off. Try a tighter crop of the clip.
 - **Depth looks inverted (near is dark)** — tick invert in the Depth panel.
 - **Changed character count and things look stale** — just hit Track again.
-

TheoreticallyPose by [Theoretically Media](#). Depth models: Depth Anything V2 + Video Depth Anything (Small, Apache-2.0) by ByteDance, served from HuggingFace. Pose: MediaPipe. Everything processes locally in your browser.
